Abstract

Background: Factor XIII (FXIII) is a heterotetramer consisting of two subunits, FXIII-A and FXIII-B. Several common gene variations were observed in FXIII-A with obvious ethnic difference. This study assessed prevalence of A614T as a common FXIII-A gene variation among Iranian patients with FXIII deficiency (FXIIID).

Materials and Methods: This study was conducted on eighty Iranian unrelated individuals with FXIIID. Genotype analysis for FXIII-A A614T gene variation was performed for all individuals.

Results: Molecular analysis of these Iranian populations revealed that all studied patients were homozygous for T allele at codon 204 of FXIII-A1 subunit.

Conclusion: Present of T allele at codon 204 of FXIII-A1 subunit among all study population can be suggestive of founder effect.

Keywords: Factor XIII, Polymorphism, Mutation

Introduction

Coagulation factor XIII (FXIII) or fibrin stabilizing factor is a zymogen composed of two A-subunits and two B-subunits that are held together no covalently in a tetrameric form (1). The gene coding FXIII-A subunit consist of 15 exons, covers a genomic region of 160 kb and maps to the 6p24-25 chromosomal region. This subunit consist of 731 amino acids and characterized by 5 domains including the activation peptide (residues of 1-37), β-sandwich (residues of 38-183), central domain or catalytic core region (residues 184-515), β-barrel 1 and 2 (residues 516- 627 and residues 628-731, respectively) (2, 3). The gene coding FXIII-B subunit located on 1q31-32, cover a 28 kb genomic region and compromise of 12 exons which separated by 11 introns. This subunit consist of 10 tandem repeats named sushi domains (2, 3). The active form of factor cross links the fibrin monomer and stabilizes the fibrin clot during the final stage of coagulation cascade. In addition, FXIII has an essential role in wound healing, angiogenesis and maintaining the pregnancy (1, 4, 5).

Until now, a considerable number of polymorphisms have been identified in FXIII-A subunits and the most common of them are Val34Leu in exon 2, Tyr204Phe in exon 5, Pro(CCA)331(CCC)Pro in exon 8, Pro564Leu, Glu(GAA)567Glu(GAG) in exon 12, Val650Ile, and Glu651Gln in exon 14. Also, in factor XIII-B subunit two common polymorphisms were reported,
His95Arg and C29759G change in intron K29756 (1-5, 8, 9). Studies on structural and functional effects of these mutations lead to better understanding causes of and accurate diagnosis of this disorder. Thus, the aim of our study is to evaluate one of the most common polymorphism of FXIII-A subunit.

**Methods**

This descriptive study was conducted on eighty unrelated Iranian patients with FXIII deficiency (FXIIID). All participants gave informed by written consent according to protocol that approved by the local medical ethics committee.

Blood sample from each patient was collected in Ethylene-diaminetetraacetic Acid (EDTA) anticoagulant tube. Blood specimens were lysed with sodium dodecyl sulfate (SDS) and genomic DNA of each sample was isolated from the leucocytes according to the standard protocol. DNA was purified using phenol–chloroform and ethanol precipitation. The quality and quantity of obtained DNA was determined through spectrophotometry and also using agarose gel electrophoresis.

After DNA extraction, genotyping of FXIII-A A614T gene variation was performed by polymerase chain reaction amplification of genomic DNA followed by restriction enzyme digestion (PCR-RFLP) (Table 1). Primer and DNA sequences were selected from reports published previously (9). For all PCR amplifications, positive control DNA samples of known genotype were included as well as a negative control without template DNA.

Results

This descriptive study was conducted on eighty patients with severe FXIID from same number of unrelated families. Among our patients, 52.5% (n: 42) were male and 47.5% (38) were female and the mean age of them was 26±3 years. In all patients, genetic analysis revealed that homozygous for T allele at codon 204 of FXIII-A1 subunit. In every case, the sequencing results agreed with the PCR-RFLP genotyping result.

Discussion

FXIII is a coagulation factor with multiple intra and extra cellular functions (1, 9, 10). Several studies revealed that there are five common gene variations in FXIII-A gene including Val34Leu, Tyr204Phe, Pro564Leu, Glu567Glu, and Glu651Gln (1-5). These common gene variations show a significant difference in various ethnicities. No comprehensive study was performed in Iranian patients with severe FXIIIID to assess' prevalence of these polymorphisms among this population.

After careful selection of study population, we chose A614T as a common mutation of FXIII-A. We found that all patients were homozygous for T allele at codon 204 of FXIII-A1 subunit.

We previously found that all of these patients were homozygote for c559t mutation in FXIII-A subunit (4, 10, 11). This mutation of a disease causing mutation and cause severe FXIIIID in Iranian patients. In fact, these two finding is a sign of founder effect in these individuals but further studies required for confirmation of this issue. A few studies were performed in Iranian patients to determined prevalence of this common polymorphism. Jeddi-Tehrani et al. were found that these common FXIII-A gene variation with a frequency of 84% in women with miscarriage and with a prevalence of 48% in healthy Iranian individuals (12). Their finding showed that this FXIII-A polymorphism is common among Iranian patients such other ethnicities in the world. A comparison with results of Jeddi-Tehrani et al. study it seems that all of our patients were inherited this common FXIII-A gene variation in similar way and further studies on FXIII-A short tandem repeat (STR) can confirm this issue that c559t mutation in FXIII-A is result from a founder effect. Meanwhile investigation of other FXIII-A common polymorphisms such as Val34Leu in exon 2, Pro(CCA)331(CCC)Pro in exon 8, Pro564Leu ,Glu (GAA)567Glu(GAG) in exon 12 as well as Val650Ile and Glu651Gln in exon 14 can be used for confirmation of founder effect in these patients (1, 13, 14).

Conclusion

Present of a similar single nucleotide polymorphism (SNP) in all of study population unlike the normal Iranian population can be suggestive of founder effect but further investigations are required for confirmation of this issue.

Acknowledgment

We appreciate all patients who precipitate in this study. This study was approved and supported by Tehran University of Medical Sciences with project number of 19076 and 26770. Authors thanks vice chancellor of Tehran University of Medical Sciences.
