Abstract:

Introduction: Oral mucositis is considered a severe complication in cancer patients receiving radiotherapy or chemotherapy for head and neck cancer. The aim of this review study was to assess the effect of low level laser therapy for prevention and management of oral mucositis in cancer patients.

Methods: The electronic databases searched included Pubmed, ISI Web of Knowledge and Google scholar with keywords as “oral mucositis”, “low level laser therapy” from 2000 to 2013.

Results: The results of most studies showed that photobiomodulation (PBM) reduced the severity of mucositis. Also, it can delay the appearance of severe mucositis.

Conclusion: Low level laser therapy is a safe approach for management and prevention of oral mucositis.

Keywords: low level laser therapy; mucositis; prevention; management.

Introduction

Oral mucositis is considered as a painful condition in patients with cancer after radiotherapy and chemotherapy. It appears as small patches to big ulceration and hemorrhage in oral mucosa ¹.

The prevalence of mucositis is 40-100% dependent on the type cancer and therapy used. In 40% of chemotherapy patients and in 100 % of radiotherapy treated patients, mucositis happened ²,³.

Oral mucositis not only damages the epithelial cells but also the local tissue reaction causes damage from reactive oxygen species and inflammatory cytokines which finally results in submucosal tissue damage. Oral mucositis appears in oral mucosa after the 5th to 10th day after chemotherapy or radiotherapy. It manifests as a burning sensation to ulcer formation that affect the quality of life of patients by producing pain and discomfort for swallowing which ultimately leads to malnutrition and dehydration ⁴.

Treatment modalities can be non-pharmacological and by pharmacological agents like lidocaine, morphine which is used as palliative care and pain relief. Non pharmacological treatments include mouthrinse, cryotherapy, etc ⁵. Recently, photobiomodulation has been used in different aspects of dentistry. photobiomodulation (PBM) is a safe, non pharmacological method which can modulate various metabolic processes via absorption of energy by chromophores ⁶.

Low level laser therapy changes the mitochondrial respiration and leads to increased ATP production which produces intracellular reactive oxygen species (ROS). These changes result in fibroblast proliferation, collagen synthesis, adjustment of inflammatory response, as well as motivation of angiogenesis and tissue repair ⁷.

There are several explanations for pain reduction
caused by PBM including modulation of the inflammatory process, alteration of excitation and nerve conduction in peripheral nerves and stimulation of release of endogenous endorphins \(^8\). So, laser therapy can be considered as a palliative treatment for this problem.

The aim of this review study was to assess the effect of low level laser therapy for prevention and management of oral mucositis in cancer patients.

**Methods**

The electronic databases searched included Pubmed, ISI Web of Knowledge and Google scholar with keywords as “oral mucositis”, “low level laser therapy” from 2000 to 2013.

The papers which are relevant were included in this review of literature.

74 articles were found, but 27 of them were selected for evaluation due to accessibility to their full texts. Also, systematic reviews and meta analysis were excluded.

**Results**

Among the 27 articles assessed, three of them were animal studies and 24 were human studies. The studies are summarized in Table 1 and Table 2. The results of most studies showed that PBM reduced the severity of mucositis. Also, it can delay the appearance of severe

Discussion

Oral mucositis is considered as a side effect of radiotherapy or chemotherapy of head and neck cancer patients. It’s necessary to standardize some protocols for prevention and management of chemotherapy or radiotherapy induced oral mucositis to prevent reduction or discontinuation of treatments. Recently, researches have focused on the effects of low level laser therapy as a new modality for managing this problem via photobiomodulation effect. Oral mucositis exhibit different biologic phases including initiation, inflammatory response, amplification/signaling, ulceration and healing. Acceleration of wound healing happens through enhanced release of growth factors, increased neovascularization and collagen formation. Some studies stated that laser can increase the production of vascular endothelial growth factor (VEGF) which results in angiogenesis and improved microcirculation and subsequently to wound healing.

Mostly, low level laser therapy was performed by diode lasers including red and infra-red wavelengths. Shorter wavelengths (632.8-660 nm) can affect the superficial layer of the epithelium but longer wavelengths penetrate deeper and affect sub-epithelial tissues. It seems that shorter wavelengths are more effective than longer ones in treatment of oral mucositis which was approved by Schubert et al. Red laser are absorbed in superficial layer of oral mucosa which is favorable for wound healing.

The effect of laser on oral mucositis showed some beneficial effects such as it delayed the time of onset, reduced the peak severity and shortened the duration of this problem. These advantages can be attributed to anti-inflammatory and analgesic effects of laser which are followed by increased local vascularity and re-epithelization of tissue. Oral wound healing can be achieved by transformation of fibroblast to myofibroblasts which promote mucosal healing. On the other hand, analgesic effects can happen through release of endorphin and eukephalin. The other mechanism of laser induced pain relief is through membrane cell depolarization, blocking the nervous impulse and fast axonal flow.

Most of studies showed the positive effect of PBM on oral mucositis but there were just two studies that reported negative effect of laser therapy. Curz et al. in assessing low level laser therapy in prevention of oral mucositis in children came to this conclusion that low level laser therapy had no beneficial effect as prophylactic option for prevention of oral mucositis.

Bjordal et al. conducted meta-analysis of the effect of low-level laser therapy (LLLT) in cancer therapy-induced oral mucositis. Despite, various laser wavelengths, parameters and dosage, they demonstrated moderate to strong evidence for efficacy of LLLT in oral mucositis management. Also, Migliorati et al. stated that LLLT can become a routine practice in management of oral mucositis to control its severity.

In assessing animal studies, anti-inflammatory effect of LLLT and wound healing was seen due to reduction in neutrophil infiltrate and cyclooxygenase-2 expression.

Other factors such as oral hygiene had influenced on prevention of oral mucositis. So, patients should be educated about oral hygiene and given instructions. Some researchers showed positive effects of good oral health on reducing the risk of severe mucositis due to decrease of oral bacteria.

One of the main factors that can enhance the prevention of oral mucositis is the ideal time of starting laser therapy which has not been clear and needs clinical trials which would evaluate and compare the different startpoints of treatment to clarify it.

According to two meta-analysis conducted about laser phototherapy in management of oral mucositis in head and neck cancers, LLLT can be used with doses of 1-6 J per point in oropharyngeal area by existence of moderate to strong evidence. For radiotherapy induced oral mucositis, a suggestion of laser therapy was possible with wavelength of 632 nm. No guideline was possible for application of LLL in management of oral mucositis in patients treated with a combined protocol of radiochemotherapy for head and neck cancer. Also, there was no possible guideline for chemotherapy induced oral mucositis due to low level of evidence.

Several studies showed positive results of LLLT for reducing the incidence and severity of mucositis accompanied by other advantages such as improved quality of life of patients. More standard investigations are needed to clarify which parameters including wavelength, energy density, time of exposure, have the best interactions with tissues to produce favorable outcomes.

Conclusion

Low level laser therapy is a noninvasive modality for prevention and management of oral mucositis with to some advantages like analgesic effect, inflammation reduction and atraumatic repeated use.
